## **Introduction to Machine Learning**

# **Advanced Risk Minimization Bias-Variance Decomposition (Deep-Dive)**

#### Learning goals

- Understand how to decompose the generalization error of a learner under L2 loss into
  - Bias of the learner
  - Variance
  - Inherent noise in the data

Generalization error of learner  $\mathcal{I}$ : Expected error of model  $\hat{f}_{\mathcal{D}_n}$ , on training sets of size n, evaluated on a fresh, random test sample.

$$GE_{n}\left(\mathcal{I}\right) = \mathbb{E}_{\mathcal{D}_{n} \sim \mathbb{P}_{xy}^{n}, (\mathbf{x}, y) \sim \mathbb{P}_{xy}}\left(L\left(y, \hat{f}_{\mathcal{D}_{n}}(\mathbf{x})\right)\right) = \mathbb{E}_{\mathcal{D}_{n}, xy}\left(L\left(y, \hat{f}_{\mathcal{D}_{n}}(\mathbf{x})\right)\right)$$

Expectation is taken over all training sets **and** independent test sample.

We assume that the data is generated by

$$y = f_{\mathsf{true}}(\mathbf{x}) + \epsilon$$

with zero-mean homoskedastic error  $\epsilon \sim (0, \sigma^2)$  independent of **x**.

By plugging in the L2 loss  $L(y, f(\mathbf{x})) = (y - f(\mathbf{x}))^2$  we get

$$GE_{n}(\mathcal{I}) = \mathbb{E}_{\mathcal{D}_{n},xy}\left(L\left(y,\hat{f}_{\mathcal{D}_{n}}(\mathbf{x})\right)\right) = \mathbb{E}_{\mathcal{D}_{n},xy}\left(\left(y-\hat{f}_{\mathcal{D}_{n}}(\mathbf{x})\right)^{2}\right)$$

$$\stackrel{\mathsf{LIE}}{=} \mathbb{E}_{xy}\left[\underbrace{\mathbb{E}_{\mathcal{D}_{n}}\left(\left(y-\hat{f}_{\mathcal{D}_{n}}(\mathbf{x})\right)^{2}\mid\mathbf{x},y\right)}_{(*)}\right]$$

Let us consider the error (\*) conditioned on one fixed test observation  $(\mathbf{x}, y)$  first. (We omit the  $|\mathbf{x}, y|$  for better readability for now.)

$$(*) = \mathbb{E}_{\mathcal{D}_n} \left( \left( y - \hat{f}_{\mathcal{D}_n}(\mathbf{x}) \right)^2 \right)$$

$$= \underbrace{\mathbb{E}_{\mathcal{D}_n} \left( y^2 \right)}_{=y^2} + \underbrace{\mathbb{E}_{\mathcal{D}_n} \left( \hat{f}_{\mathcal{D}_n}(\mathbf{x})^2 \right)}_{(1)} - 2 \underbrace{\mathbb{E}_{\mathcal{D}_n} \left( y \hat{f}_{\mathcal{D}_n}(\mathbf{x}) \right)}_{(2)}$$

by using the linearity of the expectation.

$$(*) = \mathbb{E}_{\mathcal{D}_n}\left(\left(y - \hat{f}_{\mathcal{D}_n}(\mathbf{x})\right)^2\right) = y^2 + \underbrace{\mathbb{E}_{\mathcal{D}_n}\left(\hat{f}_{\mathcal{D}_n}(\mathbf{x})^2\right)}_{(1)} - 2\underbrace{\mathbb{E}_{\mathcal{D}_n}\left(y\hat{f}_{\mathcal{D}_n}(\mathbf{x})\right)}_{(2)} =$$

Using that  $\mathbb{E}(z^2) = \text{Var}(z) + \mathbb{E}^2(z)$ , we see that

$$=y^2+\mathsf{Var}_{\mathcal{D}_n}\left(\hat{f}_{\mathcal{D}_n}(\mathbf{x})\right)+\mathbb{E}_{\mathcal{D}_n}^2\left(\hat{f}_{\mathcal{D}_n}(\mathbf{x})\right)-2y\mathbb{E}_{\mathcal{D}_n}\left(\hat{f}_{\mathcal{D}_n}(\mathbf{x})\right)$$

Plug in the definition of y

$$=\mathit{f}_{\mathsf{true}}(\mathbf{x})^2 + 2\epsilon\mathit{f}_{\mathsf{true}}(\mathbf{x}) + \epsilon^2 + \mathsf{Var}_{\mathcal{D}_n}\left(\hat{\mathit{f}}_{\mathcal{D}_n}(\mathbf{x})\right) + \mathbb{E}_{\mathcal{D}_n}^2\left(\hat{\mathit{f}}_{\mathcal{D}_n}(\mathbf{x})\right) - 2\left(\mathit{f}_{\mathsf{true}}(\mathbf{x}) + \epsilon\right)\mathbb{E}_{\mathcal{D}_n}\left(\hat{\mathit{f}}_{\mathcal{D}_n}(\mathbf{x})\right)$$

Reorder terms and use the binomial formula

$$= \epsilon^2 + \mathsf{Var}_{\mathcal{D}_n}\left(\hat{\mathit{f}}_{\mathcal{D}_n}(\mathbf{x})\right) + \left(\mathit{f}_{\mathsf{true}}(\mathbf{x}) - \mathbb{E}_{\mathcal{D}_n}\left(\hat{\mathit{f}}_{\mathcal{D}_n}(\mathbf{x})\right)\right)^2 + 2\epsilon\left(\mathit{f}_{\mathsf{true}}(\mathbf{x}) - \mathbb{E}_{\mathcal{D}_n}\left(\hat{\mathit{f}}_{\mathcal{D}_n}(\mathbf{x})\right)\right)$$

$$(*) = \epsilon^2 + \mathsf{Var}_{\mathcal{D}_n}\left(\hat{\mathit{f}}_{\mathcal{D}_n}(\boldsymbol{x})\right) + \left(\mathit{f}_{\mathsf{true}}(\boldsymbol{x}) - \mathbb{E}_{\mathcal{D}_n}\left(\hat{\mathit{f}}_{\mathcal{D}_n}(\boldsymbol{x})\right)\right)^2 + 2\epsilon\left(\mathit{f}_{\mathsf{true}}(\boldsymbol{x}) - \mathbb{E}_{\mathcal{D}_n}\left(\hat{\mathit{f}}_{\mathcal{D}_n}(\boldsymbol{x})\right)\right)$$

Let us come back to the generalization error by taking the expectation over all fresh test observations  $(\mathbf{x}, y) \sim \mathbb{P}_{xy}$ :

$$\begin{aligned} \textit{GE}_{\textit{n}}\left(\mathcal{I}\right) &= \underbrace{\sigma^{2}}_{\textit{Variance of the data}} + \mathbb{E}_{\textit{xy}} \underbrace{\left[ \textit{Var}_{\mathcal{D}_{\textit{n}}}\left(\hat{f}_{\mathcal{D}_{\textit{n}}}(\mathbf{x}) \mid \mathbf{x}, y\right) \right]}_{\textit{Variance of learner at } (\mathbf{x}, y)} \\ &+ \mathbb{E}_{\textit{xy}} \underbrace{\left[ \left( \left(f_{\textit{true}}(\mathbf{x}) - \mathbb{E}_{\mathcal{D}_{\textit{n}}}\left(\hat{f}_{\mathcal{D}_{\textit{n}}}(\mathbf{x})\right)\right)^{2} \mid \mathbf{x}, y\right) \right]}_{\textit{Squared bias of learner at } (\mathbf{x}, y)} + \underbrace{0}_{\textit{As $\epsilon$ is zero-mean and independent at }} \end{aligned}$$
