## **Introduction to Machine Learning**

# Regularization Weight Decay and L2

#### Learning goals

- L2 regularization with GD is equivalent to weight decay
- Understand how weight decay changes the optimization trajectory

#### **WEIGHT DECAY VS. L2 REGULARIZATION**

Let's optimize *L*2-regularized risk of a model  $f(\mathbf{x} \mid \theta)$ 

$$\min_{oldsymbol{ heta}} \mathcal{R}_{\mathsf{reg}}(oldsymbol{ heta}) = \min_{oldsymbol{ heta}} \mathcal{R}_{\mathsf{emp}}(oldsymbol{ heta}) + rac{\lambda}{2} \|oldsymbol{ heta}\|_2^2$$

by GD. The gradient is

$$abla_{m{ heta}} \mathcal{R}_{\mathsf{reg}}(m{ heta}) = 
abla_{m{ heta}} \mathcal{R}_{\mathsf{emp}}(m{ heta}) + \lambda m{ heta}$$

We iteratively update  $\theta$  by step size  $\alpha$  times the negative gradient

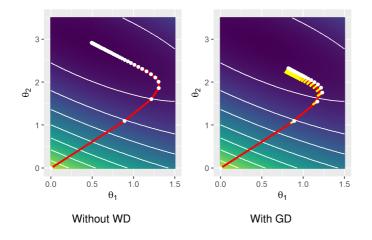

$$\begin{aligned} \boldsymbol{\theta}^{[\mathsf{new}]} &= \boldsymbol{\theta}^{[\mathsf{old}]} - \alpha \left( \nabla_{\boldsymbol{\theta}} \mathcal{R}_{\mathsf{emp}}(\boldsymbol{\theta}^{[\mathsf{old}]}) + \lambda \boldsymbol{\theta}^{[\mathsf{old}]} \right) \\ &= \boldsymbol{\theta}^{[\mathsf{old}]} (\mathbf{1} - \alpha \lambda) - \alpha \nabla_{\boldsymbol{\theta}} \mathcal{R}_{\mathsf{emp}}(\boldsymbol{\theta}^{[\mathsf{old}]}) \end{aligned}$$

We see how  $\theta^{[old]}$  decays in magnitude – for small  $\alpha$  and  $\lambda$  – before we do the gradient step. Performing the decay directly, under this name, is a very well-known technique in DL - and simply L2 regularization in disguise (for GD).

### **WEIGHT DECAY VS. L2 REGULARIZATION / 2**

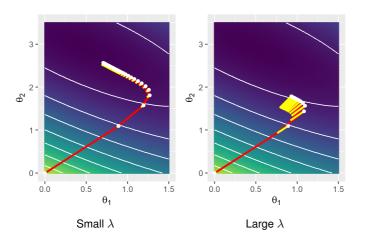

In GD With WD, we slide down neg. gradients of  $\mathcal{R}_{\text{emp}},$  but in every step, we are pulled back to origin.

### WEIGHT DECAY VS. L2 REGULARIZATION / 3

How strongly we are pulled back (for fixed  $\alpha$ ) depends on  $\lambda$ :

#### **CAVEAT AND OTHER OPTIMIZERS**

**Caveat**: Equivalence of weight decay and L2 only holds for (S)GD!

- Hanson and Pratt 1988 originally define WD "decoupled" from gradient-updates  $\alpha \nabla_{\theta} \mathcal{R}_{\text{emp}}(\theta^{[\text{old}]})$  as  $\theta^{[\text{new}]} = \theta^{[\text{old}]}(1 \lambda') \alpha \nabla_{\theta} \mathcal{R}_{\text{emp}}(\theta^{[\text{old}]})$
- This is equivalent to modern WD/L2 (last slide) using reparameterization  $\lambda'=\alpha\lambda$
- Consequence: if there is optimal  $\lambda'$ , then optimal L2 penalty is tightly coupled to  $\alpha$  as  $\lambda = \lambda'/\alpha$  (and vice versa)
- Loshchilov and Hutter 2019 show no equivalence of *L*2 and WD possible for adaptive methods like Adam (Prop. 2)
- In many cases where SGD+L2 works well, Adam+L2 underperforms due to non-equivalence with WD
- They propose a variant of Adam decoupling WD from gradient updates (AdamW), increasing performance over Adam+L2
